The authors have attempted to correlate the CT densitometric analysis with the histologic pattern of the neoplastic lesion in order to use it for the differential diagnosis. Thirty-seven patients affected by different neoplasms were studied. Lung density measurements were performed by a CT densitometric analysis of planimetric regions with a diameter of 1 cm; three slices were examined in each patient. Histologically, seven lesions were classified as being typical adenocarcinomas, seven as squamous cell carcinomas, ten as large cell non-small cell carcinomas, and ten as undifferentiated carcinomas. All the typical adenocarcinomas appeared as hyperdense neoplasms, the squamous cell carcinomas and the large cell non-small cell carcinomas as isodense neoplasms and the undifferentiated carcinomas as hypodense neoplasms. The histologic pattern and the CT densitometric analysis of the neoplasms were correlated in the patients with a neoplastic mass of an appropriate size./ * * Copyright 2017-2020 Crown Copyright * * Licensed under the Apache License, Version 2.0 (the "License"); * you may not use this file except in compliance with the License. * You may obtain a copy of the License at * * * * Unless required by applicable law or agreed to in writing, software * distributed under the License is distributed on an "AS IS" BASIS, * WITHOUT WARRANTIES OR CONDITIONS 2d92ce491b
