Packet-based and circuit-switched communication systems are generally well-known in the communications art. Circuit-switched systems are those systems where each user has an assigned channel or channel pair, on which the user receives all transmissions. Packet-based systems, on the other hand, are those systems where each user has access to a shared communications channel through which it can send and receive variable sized messages called packets. Examples of packet-based systems include wireless cellular networks, local and wide area networks (LANs and WANs), and so forth. A number of applications, such as voice, interactive games, multi-media streaming of entertainment content, and the like, may advantageously employ packet-based communications. In packet-based systems, such as LANs, WANs, and cellular networks, data transfers are generally accomplished through the transmission of data packets over a communications medium. Data packets are typically formatted for delivery to a particular destination, such as a receiving device or destination server. The speed and reliability of communications in a packet-based system are critical to the performance of such systems. When packets take too long to reach their destination, delays can occur when packets are late or lost. In some cases, these delays can be only a few seconds, but in other cases they can be tens of seconds, minutes, hours, or even days. A delay in the data flow, however, can have disastrous consequences on the efficiency and reliability of packet-based systems. For example, because data flow speeds for different types of applications often require different speeds, individual packets of one type of application may be delayed 570a42141b
